1. Objetivos

Validar, calibrar y en su caso adaptar y adecuar el sistema computacional para el diseño de riego por gravedad desarrollado durante 2014.

2. Antecedentes

Durante 2014 se desarrolló un software que permite realizar la caracterización hidrodinámica de suelos a partir de los datos de una prueba de avance de riego y de la granulometría del suelo, dicho software también realiza el cálculo del gasto óptimo de riego. A la fecha se hace necesario calibrar y validar el software de tal forma que se encuentre en condiciones de ser transferido a los usuarios potenciales.

3. Resultados

3.1. Análisis de las variaciones del frente de avance en riego por gravedad en relación con cambios en la conductividad hidráulica a saturación.

- A) Variación del frente de avance en riego (ks 3.0 hf 10.0)
- B) Variación del frente de avance en riego (ks 3.0 hf 20.0)
- C) Variación del frente de avance en riego (ks 3.0 hf 30.0)
- D) Variación del frente de avance en riego (ks 3.0 hf 40.0)
- E) Variación del frente de avance en riego (ks 3.0 hf 50.0)
- F) Variación del frente de avance en riego (ks 3.0 hf 60.0)

Ilustración 1.- Variación del frente de avance en riego (ks 3.0 hf 10.0).

Ilustración 2.- Variación del frente de avance en riego (ks 3.0 hf 20.0).

Ilustración 3.- Variación del frente de avance en riego (ks 3.0 hf 30.0).

Ilustración 4.- Variación del frente de avance en riego (ks 3.0 hf 40.0).

Ilustración 5.- Variación del frente de avance en riego (ks 3.0 hf 50.0).

Ilustración 6.- Variaciones del frente de avance en riego (ks 3.0 hf 60.0)

3.2. Análisis del efecto del cambio en la escala de presiones de la ecuación de Green y Ampt sobre la posición del frente de avance en riego por gravedad.

- A) hf 10 ks 0.5
- B) hf 10 ks 1.0
- C) hf 10 ks 2.0
- D) hf 10 ks 3.0
- E) hf 10 ks 4.0
- F) hf 10 ks 4.25

3.3. Sistematización de resultados de modelaciones de eventos de riego por gravedad.

El objetivo del diseño de riego por gravedad es conseguir la aplicación de una lámina de riego requerida por el cultivo de la manera más uniforme posible conservando una eficiencia de aplicación alta. El diseño del riego consiste en determinar el gasto de aporte y el tiempo durante el cual se aplica dicho gasto en la cabecera de la melga para lograr la mayor uniformidad posible es decir, en determinar el gasto óptimo, para una longitud de melga específica y una caracterización hidrodinámica del suelo.

En el IMTA se han desarrollado dos modelos para simulación del riego por gravedad, uno de ellos basado en el empleo de las ecuaciones de Saint-Venant y Richards y el otro es una forma simplificada en la cual en lugar de usar la ecuación de Richards para el cálculo de la infiltración del agua en el suelo, se hace uso de la ecuación de Green y Ampt, lo cual representa una reducción significativa en el tiempo de cómputo requerido para la ejecución de los cálculos. Se hace necesario comparar los resultados que se obtienen mediante la aplicación e ambos modelos para el cálculo del gasto óptimo de riego en diez tipos de suelos seleccionados de acuerdo con el triángulo de las texturas, a fin de conocer el grado de aproximación que tiene el modelo simplificado con respecto al modelo hidrodinámico completo.

A) Resultados de láminas de riego

B) Diseño de riego con el modelo Saint Venant y Green y Ampt y el modelo Saint Venant y Richards

Se obtuvieron cuadros de diseño a partir de la sistematización de modelaciones de eventos de riego, dichos cuadros se muestran a continuación. Se calcularon las diferencias entre los gastos de riego que proporcionan cada uno de los cuadros (gráfica 31) y se observó que la diferencia entre los resultados crece conforme aumenta el contenido de arcilla en el suelo.

B) Aplicación para tres tipos de suelos contrastantes

Se verifica que el proceso de asignación de valores iniciales funcione bien para tres tipos de suelos contrastantes: limo, arcilla y franco arenoso. A continuación se muestran los resultados correspondientes:

Suelo Arcilla

Ilustración 44.- Iteración 1 de Levenberg-Marquardt para Suelo Arcilla.

Tabla 1. Primera iteración Levenberg-Marquardt para suelo arcilla.

3.5. Cálculo de evolución del error cuadrático medio en pruebas de avance de riego por gravedad en un suelo franco.

El objetivo del diseño de riego por melgas es conseguir la aplicación de una lámina de riego requerida por el cultivo de la manera más uniforme posible, conservando una eficiencia de aplicación alta. El diseño del riego consiste en determinar el gasto de aporte y el tiempo durante el cual se aplica dicho gasto en la cabecera de la melga para lograr la mayor uniformidad posible; es decir, en determinar el gasto óptimo para una longitud de melga específica y una caracterización hidrodinámica del suelo dada. Para realizar dicha caracterización hidrodinámica puede utilizarse por ejemplo, información de una prueba de avance de riego, a partir de la cual se realiza el procedimiento de ajuste u optimización de los parámetros buscando minimizar el error obtenido entre las observaciones realizadas y las obtenidas mediante el modelo empleado para la simulación de la fase de avance del riego por gravedad.

En este sentido, se verificó la evolución del error cuadrático medio en un suelo franco a partir de asignaciones automáticas de los valores iniciales en el proceso de optimización de parámetros.

4. Conclusiones

Se calibró y validó un software que permite: a) estimar parámetros de infiltración a partir de pruebas de avance de riego por melgas, y b) realizar el cálculo del gasto óptimo de riego a partir de datos de pruebas de avance y de la granulometría del suelo.
